## TRI-SUBSTITUTED HETEROARYLS AND METHODS OF MAKING AND USING THE SAME

### BACKGROUND OF THE INVENTION

TGF $\beta$  (Transforming Growth Factor  $\beta$ ) is a member of a large family of dimeric polypeptide growth factors that includes, for example, activins, inhibins, bone morphogenetic proteins (BMPs), growth and differentiation factors (GDFs) and mullerian inhibiting substance (MIS). TGF $\beta$  exists in three isoforms (TGF $\beta$ 1, TGF $\beta$ 2, and TGF $\beta$ 3) and is present in most cells, along with its receptors. Each isoform is expressed in both a tissue-specific and developmentally regulated fashion. Each TGF $\beta$  isoform is synthesized as a precursor protein that is cleaved intracellularly into a C-terminal region (latency associated peptide (LAP)) and an N-terminal region known as mature or active TGF $\beta$ . LAP is typically non-covalently associated with mature TGF $\beta$  prior to secretion from the cell. The LAP- TGF $\beta$  complex cannot bind to the TGF $\beta$  receptors and is not biologically active. TGF $\beta$  is generally released (and activated) from the complex by a variety of mechanisms including, for example, interaction with thrombospondin-1 or plasmin.

Following activation, TGF $\beta$  binds at high affinity to the type II receptor (TGF $\beta$ RII), a constitutively active serine/threonine kinase. The ligand-bound type II receptor phosphorylates the TGF $\beta$  type I receptor (Alk 5) in a glycine/serine rich domain, which allows the type I receptor to recruit and phosphorylate downstream signaling molecules, Smad2 or Smad3. See, e.g., Huse, M. et al., *Mol. Cell.* 8: 671-682 (2001). Phosphorylated Smad2 or Smad3 can then complex with Smad4, and the entire hetero-Smad complex translocates to the nucleus and regulates transcription of various TGF $\beta$ -responsive genes. See, e.g., Massagué, J. *Ann. Rev. Biochem. Med.* 67: 773 (1998).

Activins are also members of the TGF $\beta$  superfamily, which are distinct from TGF $\beta$  in that they are homo- or heterodimers of activin  $\beta$ a or  $\beta$ b. Activins signal in a manner similar to TGF $\beta$ , that is, by binding to a constitutive serine-threonine receptor kinase, activin type II receptor (ActRIIB), and activating a type I serine-threonine receptor, Alk 4, to phosphorylate Smad2 or Smad3. The consequent formation of a hetero-Smad complex with Smad4 also results in the activin-induced regulation of gene transcription.

Indeed, TGF $\beta$  and related factors such as activin regulate a large array of cellular processes, e.g., cell cycle arrest in epithelial and hematopoietic cells, control of

-2-

mesenchymal cell proliferation and differentiation, inflammatory cell recruitment, immunosuppression, wound healing, and extracellular matrix production. See, e.g., Massagué, J. *Ann. Rev. Cell. Biol.* 6: 594-641 (1990); Roberts, A. B. and Sporn M. B. *Peptide Growth Factors and Their Receptors*, 95: 419-472 Berlin: Springer-Verlag (1990); Roberts, A. B. and Sporn M. B. *Growth Factors* 8:1-9 (1993); and Alexandrow, M. G., Moses, H. L. *Cancer Res.* 55: 1452-1457 (1995). Hyperactivity of TGF $\beta$  signaling pathway underlies many human disorders (e.g., excess deposition of extracellular matrix, an abnormally high level of inflammatory responses, fibrotic disorders, and progressive cancers). Similarly, activin signaling and overexpression of activin is linked to

10 pathological disorders that involve extracellular matrix accumulation and fibrosis (see, e.g., Matsuse, T. et al., *Am. J. Respir. Cell Mol. Biol.* 13: 17-24 (1995); Inoue, S. et al., *Biochem. Biophys. Res. Comm.* 205: 441-448 (1994); Matsuse, T. et al, *Am. J. Pathol.* 148: 707-713 (1996); De Bleser et al., *Hepatology* 26: 905-912 (1997); Pawlowski, J.E., et al., *J. Clin. Invest.* 100: 639-648 (1997); Sugiyama, M. et al., *Gastroenterology* 114: 550-558

15 (1998); Munz, B. et al., *EMBO J.* 18: 5205-5215 (1999)), inflammatory responses (see, e.g., Rosendahl, A. et al., *Am. J. Respir. Cell Mol. Biol.* 25: 60-68 (2001)), cachexia or wasting (see Matzuk, M. M. et al., *Proc. Nat. Acad. Sci. USA* 91: 8817-8821 (1994); Coerver, K.A. et al, *Mol. Endocrinol.* 10: 534-543 (1996); Cipriano, S.C. et al. *Endocrinology* 141: 2319-27 (2000)), diseases of or pathological responses in the central

20 nervous system (see Logan, A. et al. *Eur. J. Neurosci.* 11: 2367-2374 (1999); Logan, A. et al. *Exp. Neurol.* 159: 504-510 (1999); Masliah, E. et al., *Neurochem. Int.* 39: 393-400 (2001); De Groot, C. J. A. et al, *J. Neuropathol. Exp. Neurol.* 58: 174-187 (1999), John, G. R. et al, *Nat Med.* 8: 1115-21 (2002)) and hypertension (see Dahly, A. J. et al., *Am. J. Physiol. Regul. Integr. Comp. Physiol.* 283: R757-67 (2002)). Studies have shown that

25 TGF $\beta$  and activin can act synergistically to induce extracellular matrix production (see, e.g., Sugiyama, M. et al., *Gastroenterology* 114: 550-558, (1998)). It is therefore desirable to develop modulators (e.g., antagonists) to members of the TGF $\beta$  family to prevent and/or treat disorders involving this signaling pathway.

### SUMMARY OF THE INVENTION

30 The invention is based on the discovery that compounds of formula (I) are unexpectedly potent antagonists of the TGF $\beta$  family type I receptors, Alk5 and/or Alk 4.

Thus, compounds of formula (I) can be employed in the prevention and/or treatment of diseases such as fibrosis (e.g., renal fibrosis, pulmonary fibrosis, and hepatic fibrosis), progressive cancers, or other diseases for which reduction of TGF $\beta$  family signaling activity is desirable.

Some compounds of formula (I) exhibit IC<sub>50</sub> and K<sub>i</sub> values of less than 1  $\mu$ M (such as below 50 nM).

Compounds of formula (I) can also be modified by appending appropriate functionalities to enhance selective biological properties. 10 As used herein, an effective amount is defined as the amount required to confer a therapeutic effect on the treated patient, and is typically determined based on age, surface area, weight, and condition of the patient. The interrelationship of dosages for animals and humans (based on milligrams per meter squared of body surface) is described by Freireich et al., *Cancer Chemother. Rep.*, 50: 219 (1966). Body surface area may be approximately  
15 determined from height and weight of the patient. See, e.g., Scientific Tables, Geigy Pharmaceuticals, Ardsley, New York, 537 (1970). As used herein, “patient” refers to a mammal, including a human.

An antagonist, as used herein, is a molecule that binds to the receptor without activating the receptor. It competes with the endogenous ligand(s) or substrate(s) for  
20 binding site(s) on the receptor and, thus inhibits the ability of the receptor to transduce an intracellular signal in response to endogenous ligand binding.

As compounds of formula (I) are antagonists of TGF $\beta$  receptor type I (Alk5) and/or activin receptor type I (Alk4), these compounds are useful in inhibiting the consequences of TGF $\beta$  and/or activin signal transduction such as the production of extracellular matrix  
25 (e.g., collagen and fibronectin), the differentiation of stromal cells to myofibroblasts, and the stimulation of and migration of inflammatory cells. Thus, compounds of formula (I) inhibit pathological inflammatory and fibrotic responses and possess the therapeutic utility of treating and/or preventing disorders or diseases for which reduction of TGF $\beta$  and/or  
activin activity is desirable (e.g., various types of fibrosis or progressive cancers). In  
30 addition, the compounds of formula (I) are useful for studying and researching the role of TGF $\beta$  receptor type I (Alk5) and/or activin receptor type I (Alk4), such as their role in

-14-

cellular processes, for example, signal transduction, production of extracellular matrix, the differentiation of stromal cells to myofibroblasts, and the stimulation of and migration of inflammatory cells.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In addition, the materials, methods, and examples are illustrative only and not intended to be limiting.

Other features and advantages of the invention will be apparent from the following detailed description, and from the claims.

### DETAILED DESCRIPTION OF THE INVENTION

In general, the invention features compounds of formula (I), which exhibit surprisingly high affinity for the TGF $\beta$  family type I receptors, Alk 5 and/or Alk 4.

#### Synthesis of the Compounds of formula (I)

Compounds of formula (I) may be prepared by a number of known methods from commercially available or known starting materials. In one method, compounds of formula (I) wherein A<sup>1</sup> is N and A<sup>2</sup> is NH, or A<sup>1</sup> is NH and A<sup>2</sup> is N are prepared according to Scheme 1a or Scheme 1b below. Specifically, in Scheme 1a, optionally substituted 2-methylpyridine (II) is deprotonated by LDA before reacting with R<sup>1</sup>-substituted carboxylic acid methoxy-methyl-amide (V) to form an R<sup>1</sup>-(6-methylpyridyl)-ketone (III). R<sup>1</sup> has been defined above. See Example 3B below. The methoxy-methyl-amide can be prepared by reacting a corresponding acid chloride (i.e., R<sup>1</sup>-CO-Cl) with *N,O*-dimethylhydroxylamine hydrochloride. See Example 2 below. The R<sup>1</sup>-(6-methylpyridyl)-ketone (III) can then be treated with sodium nitrite in acetic acid to afford an  $\alpha$ -keto-oxime (IV), which can undergo further reaction with an appropriate substituted (and optionally protected) aldehyde (VI) in the presence of ammonium acetate to yield a compound of formula (I).

Scheme 1a

-15-

In another method, the above-described compounds of formula (I) can be prepared according to Scheme 1b below. Specifically,  $R^1$ -substituted pyridine-2-carbaldehyde (IIa) is first reacted with aniline and diphenyl phosphite to form a resulting *N,P*-acetal, which can further couple with an  $R^1$ -substituted aldehyde to produce an  $(R^1$ -methyl)-pyridyl-ketone (IIIa). See, e.g., Journet et al., *Tetrahedron Lett.* 39:1717-1720 (1998) and Example 3C below. Treatment of the  $(R^1$ -methyl)-pyridyl-ketone (IIIa) with sodium nitrite in acetic acid produces an  $\alpha$ -keto-oxime (IVa), which can undergo reaction with an appropriate substituted (and optionally protected) aldehyde (VI) to yield a compound of formula (I) as described in Scheme 1a above.

Scheme 1b

-16-

If compound (VI) is in its protected form, appropriate deprotecting agents can be applied to the resulting compound after the coupling reaction of compound (IV) or (IVa) and compound (VI) to yield a compound of formula (I). See, e.g., T. W. Greene, *Protective Groups in Organic Synthesis*, John Wiley & Sons, Inc., New York (1981), for suitable protecting groups.

Alternatively, a compound of formula (I) can be prepared by reacting intermediate (IV) or (IVa) with an aldehyde (VII) to yield a further intermediate (VIII), which can then react with compound (IX) to yield a compound of formula (I). Note that moieties  $Y'$  and  $Y''$  are precursors of moiety  $Y$ . See Scheme 2 below. In addition, desired substitutions at  $R^a$  can be obtained by selecting, for example, the appropriate compound (IIa) intermediate. See, e.g., Example 3A below.

-17-

Scheme 2

In some embodiments, moiety X in compound (VII) is a nitrogen-containing heterocycloalkyl (e.g., piperidine). The nitrogen ring atom can be protected by a nitrogen protecting group (e.g., Cbz, Boc, or Fmoc) before coupling to compound (IV) or (IVa) and deprotected afterwards (see first step of Scheme 3) to yield compound (VIIIa). This compound can further react with various compounds (IX) to produce a compound of formula (I). See second steps of Scheme 3 below. It should be noted that compound (VIII) or compound (VIIIa) can be a compound of formula (I) as well.

-18-

## Scheme 3

Similarly, when moiety X in compound (VII) is a cycloalkyl (e.g., cyclopentyl, cyclohexyl, or bicyclo[2.2.2]octane), it can be further functionalized to form a compound of formula (I) as depicted in Schemes 4, 5a, 5b, and 5c below.

Compounds of formula (I) wherein  $A^1$  is N and  $A^2$  is  $NR^b$  (or  $A^1$  is  $NR^b$  and  $A^2$  is N) can be prepared by known methods. For example, compounds of formula (I) with an unsubstituted imidazolyl core ring can be treated with  $R^bI$  and  $CsCO_3$  to produce a compound of formula (I) having a substituted imidazolyl core ring. See, e.g., Liverton, et al., *J. Med. Chem.*, 42: 2180-2190 (1999).

Compounds of formula (I) wherein  $A^1$  is O and  $A^2$  is NH (or  $A^1$  is NH and  $A^2$  is O) or wherein  $A^1$  is S and  $A^2$  is NH (or  $A^1$  is NH and  $A^2$  is S), can be prepared according to known methods. One of these methods employs the same intermediate (III) or (IIIa) as

-24-

described above. See, e.g., Revesz, et al., *Bioorg. & Med. Chem. Lett.* 10: 1261-1264 (2000) and Scheme 6 below.

Scheme 6

As is well known to a skilled person in chemistry, desired substitutions can be placed on the 2-pyridyl ring in the last step of the synthesis. See, e.g., Example 24 below.

-25-

As discussed above, hyperactivity of the TGF $\beta$  family signaling pathways can result in excess deposition of extracellular matrix and increased inflammatory responses, which can then lead to fibrosis in tissues and organs (e.g., lung, kidney, and liver) and ultimately result in organ failure. See, e.g., Border, W.A. and Ruoslahti E. *J. Clin. Invest.* 90: 1-7 (1992) and Border, W.A. and Noble, N.A. *N. Engl. J. Med.* 331: 1286-1292 (1994). Studies have been shown that the expression of TGF $\beta$  and/or activin mRNA and the level of TGF $\beta$  and/or activin are increased in patients suffering from various fibrotic disorders, e.g., fibrotic kidney diseases, alcohol-induced and autoimmune hepatic fibrosis, myelofibrosis, bleomycin-induced pulmonary fibrosis, and idiopathic pulmonary fibrosis.

Compounds of formula (I), which are antagonists of the TGF $\beta$  family type I receptors Alk 5 and/or Alk 4, and inhibit TGF $\beta$  and/or activin signaling pathway, are therefore useful for treating and/or preventing fibrotic disorders or diseases mediated by an increased level of TGF $\beta$  and/or activin activity. As used herein, a compound inhibits the TGF $\beta$  family signaling pathway when it binds (e.g., with an IC<sub>50</sub> value of less than 10  $\mu$ M; such as, less than 1  $\mu$ M; and for example, less than 5 nM) to a receptor of the pathway (e.g., Alk 5 and/or Alk 4), thereby competing with the endogenous ligand(s) or substrate(s) for binding site(s) on the receptor and reducing the ability of the receptor to transduce an intracellular signal in response to the endogenous ligand or substrate binding. The aforementioned disorders or diseases include any condition (a) marked by the presence of an abnormally high level of TGF $\beta$  and/or activin; and/or (b) an excess accumulation of extracellular matrix; and/or (c) an increased number and synthetic activity of myofibroblasts. These disorders or diseases include, but are not limited to, fibrotic conditions such as scleroderma, idiopathic pulmonary fibrosis, glomerulonephritis, diabetic nephropathy, lupus nephritis, hypertension-induced nephropathy, ocular or corneal scarring, hepatic or biliary fibrosis, acute lung injury, pulmonary fibrosis, post-infarction cardiac fibrosis, fibrosclerosis, fibrotic cancers, fibroids, fibroma, fibroadenomas, and fibrosarcomas. Other fibrotic conditions for which preventive treatment with compounds of formula (I) can have therapeutic utility include radiation therapy-induced fibrosis, chemotherapy-induced fibrosis, and surgically induced scarring including surgical adhesions, laminectomy, and coronary restenosis.

-26-

Increased TGF $\beta$  activity is also found to manifest in patients with progressive cancers. Studies have shown that in late stages of various cancers, both the tumor cells and the stromal cells within the tumors generally overexpress TGF $\beta$ . This leads to stimulation of angiogenesis and cell motility, suppression of the immune system, and increased  
5 interaction of tumor cells with the extracellular matrix. See, e.g., Hojo, M. et al., *Nature* 397: 530-534 (1999). As a result, the tumor cells become more invasive and metastasize to distant organs. See, e.g., Maehara, Y. et al., *J. Clin. Oncol.* 17: 607-614 (1999) and Picon, A. et al., *Cancer Epidemiol. Biomarkers Prev.* 7: 497-504 (1998). Thus, compounds of formula (I), which are antagonists of the TGF $\beta$  type I receptor and inhibit TGF $\beta$  signaling  
10 pathways, are also useful for treating and/or preventing various late stage cancers which overexpress TGF $\beta$ . Such late stage cancers include carcinomas of the lung, breast, liver, biliary tract, gastrointestinal tract, head and neck, pancreas, prostate, cervix as well as multiple myeloma, melanoma, glioma, and glioblastomas.

Importantly, it should be pointed out that because of the chronic, and in some cases  
15 localized, nature of disorders or diseases mediated by overexpression of TGF $\beta$  and/or activin (e.g., fibrosis or cancers), small molecule treatments (such as treatment disclosed in the present invention) are favored for long-term treatment.

Not only are compounds of formula (I) useful in treating disorders or diseases mediated by high levels of TGF $\beta$  and/or activin activity, these compounds can also be used  
20 to prevent the same disorders or diseases. It is known that polymorphisms leading to increased TGF $\beta$  and/or activin production have been associated with fibrosis and hypertension. Indeed, high serum TGF $\beta$  levels are correlated with the development of fibrosis in patients with breast cancer who have received radiation therapy, chronic graft-versus-host-disease, idiopathic interstitial pneumonitis, veno-occlusive disease in  
25 transplant recipients, and peritoneal fibrosis in patients undergoing continuous ambulatory peritoneal dialysis. Thus, the levels of TGF $\beta$  and/or activin in serum and of TGF $\beta$  and/or activin mRNA in tissue can be measured and used as diagnostic or prognostic markers for disorders or diseases mediated by overexpression of TGF $\beta$  and/or activin, and polymorphisms in the gene for TGF $\beta$  that determine the production of TGF $\beta$  and/or activin  
30 can also be used in predicting susceptibility to disorders or diseases. See, e.g., Blobel, G.C. et al., *N. Engl. J. Med.* 342(18): 1350-1358 (2000); Matsuse, T. et al., *Am. J. Respir. Cell*

5 Administration of Compounds of formula (I)

As defined above, an effective amount is the amount required to confer a therapeutic effect on the treated patient. For a compound of formula (I), an effective amount can range, for example, from about 1 mg/kg to about 150 mg/kg (e.g., from about 1 mg/kg to about 100 mg/kg). Effective doses will also vary, as recognized by those skilled in the art, dependant on route of administration, excipient usage, and the possibility of co-usage with other therapeutic treatments including use of other therapeutic agents and/or radiation therapy.

Compounds of formula (I) can be administered in any manner suitable for the administration of pharmaceutical compounds, including, but not limited to, pills, tablets, capsules, aerosols, suppositories, liquid formulations for ingestion or injection or for use as eye or ear drops, dietary supplements, and topical preparations. The pharmaceutically acceptable compositions include aqueous solutions of the active agent, in an isotonic saline, 5% glucose or other well-known pharmaceutically acceptable excipient. Solubilizing agents such as cyclodextrins, or other solubilizing agents well-known to those familiar with the art, can be utilized as pharmaceutical excipients for delivery of the therapeutic compounds. As to route of administration, the compositions can be administered orally, intranasally, transdermally, intradermally, vaginally, intraaurally, intraocularly, buccally, rectally, transmucosally, or via inhalation, implantation (e.g., surgically), or intravenous administration. The compositions can be administered to an animal (e.g., a mammal such as a human, non-human primate, horse, dog, cow, pig, sheep, goat, cat, mouse, rat, guinea pig, rabbit, hamster, gerbil, or ferret, or a bird, or a reptile, such as a lizard).

Optionally, compounds of formula (I) can be administered in conjunction with one or more other agents that inhibit the TGF $\beta$  signaling pathway or treat the corresponding pathological disorders (e.g., fibrosis or progressive cancers) by way of a different mechanism of action. Examples of these agents include angiotensin converting enzyme

-28-

inhibitors, nonsteroid and steroid anti-inflammatory agents, as well as agents that antagonize ligand binding or activation of the TGF $\beta$  receptors, e.g., anti-TGF $\beta$ , anti-TGF $\beta$  receptor antibodies, or antagonists of the TGF $\beta$  type II receptors.

The invention will be further described in the following examples, which do not  
5 limit the scope of the invention described in the claims.

The TGF $\beta$  inhibitory activity of compounds of formula (I) can be assessed by methods described in the following examples.

-73-

**Example 215****Cell-Free Assay for Evaluating Inhibition of Autophosphorylation of TGF $\beta$  Type I Receptor**

The serine-threonine kinase activity of TGF $\beta$  type I receptor was measured as the autophosphorylation activity of the cytoplasmic domain of the receptor containing an N-terminal poly histidine, TEV cleavage site-tag, e.g., His-TGF $\beta$ RI. The His-tagged receptor cytoplasmic kinase domains were purified from infected insect cell cultures using the Gibco-BRL FastBac HTb baculovirus expression system.

To a 96-well Nickel FlashPlate (NEN Life Science, Perkin Elmer) was added 20  $\mu$ l of 1.25  $\mu$ Ci  $^{33}$ P-ATP/25  $\mu$ M ATP in assay buffer (50 mM Hepes, 60 mM NaCl, 1 mM MgCl<sub>2</sub>, 2 mM DTT, 5 mM MnCl<sub>2</sub>, 2% glycerol, and 0.015% Brij<sup>®</sup> 35). 10  $\mu$ l of each test compound of formula (I) prepared in 5% DMSO solution were added to the FlashPlate. The assay was then initiated with the addition of 20  $\mu$ l of assay buffer containing 12.5 pmol of His-TGF $\beta$ RI to each well. Plates were incubated for 30 minutes at room temperature and the reactions were then terminated by a single rinse with TBS. Radiation from each well of the plates was read on a TopCount (Packard). Total binding (no inhibition) was defined as counts measured in the presence of DMSO solution containing no test compound and non-specific binding was defined as counts measured in the presence of EDTA or no-kinase control.

Alternatively, the reaction performed using the above reagents and incubation conditions but in a microcentrifuge tube was analyzed by separation on a 4-20% SDS-PAGE gel and the incorporation of radiolabel into the 40 kDa His-TGF $\beta$ RI SDS-PAGE band was quantitated on a Storm Phosphoimager (Molecular Dynamics).

Compounds of formula (I) typically exhibited IC<sub>50</sub> values of less than 10  $\mu$ M; some exhibited IC<sub>50</sub> values of less than 1  $\mu$ M; and some even exhibited IC<sub>50</sub> values of less than 50 nM.

**Example 216****Cell-Free Assay for Evaluating Inhibition of Activin Type I Receptor Kinase Activity**

Inhibition of the Activin type I receptor (Alk 4) kinase autophosphorylation activity by test compounds of formula (I) can be determined in a similar manner to that described

-74-

above in Example 215 except that a similarly His-tagged form of Alk 4 (His-Alk 4) is used in place of the His-TGF $\beta$ RI.

50 nM of tritiated 4-(3-pyridin-2-yl-1H-pyrazol-4-yl)-quinoline (custom-ordered from PerkinElmer Life Science, Inc., Boston, MA) in assay buffer (50 mM Hepes, 60 mM NaCl<sub>2</sub>, 1 mM MgCl<sub>2</sub>, 5 mM MnCl<sub>2</sub>, 2 mM 1,4-dithiothreitol (DTT), 2% Brij<sup>®</sup> 35; pH 7.5) was premixed with a test compound of formula (I) in 1% DMSO solution in a v-bottom plate. Control wells containing either DMSO without any test compound or control compound in DMSO were used. To initiate the assay, His-TGF $\beta$  Type I receptor in the same assay buffer (Hepes, NaCl<sub>2</sub>, MgCl<sub>2</sub>, MnCl<sub>2</sub>, DTT, and 30% Brij<sup>®</sup> added fresh) was added to a nickel coated FlashPlate (PE, NEN catalog number: SMP107), while the control wells contained only buffer (i.e., no His-TGF $\beta$  Type I receptor). The premixed solution of tritiated 4-(3-pyridin-2-yl-1H-pyrazol-4-yl)-quinoline and test compound of formula (I) was then added to the wells. The wells were aspirated after an hour at room temperature and radioactivity in wells (emitted from the tritiated compound) was measured using TopCount (PerkinElmer Lifesciences, Inc., Boston MA).

Compounds of formula (I) typically exhibited K<sub>i</sub> values of less than 10  $\mu$ M; some exhibited K<sub>i</sub> values of less than 1  $\mu$ M; and some even exhibited K<sub>i</sub> values of less than 50 nM.

##### **Assay for Evaluating Cellular Inhibition of TGF $\beta$ Signaling and Cytotoxicity**

25        Biological activity of the compounds of formula (I) was determined by measuring their ability to inhibit TGF $\beta$ -induced PAI-Luciferase reporter activity in HepG2 cells.

HepG2 cells were stably transfected with the PAI-luciferase reporter grown in DMEM medium containing 10% FBS, penicillin (100 U/ml), streptomycin (100  $\mu$ g/ml), L-glutamine (2 mM), sodium pyruvate (1 mM), and non-essential amino acids (1x). The transfected cells were then plated at a concentration of 2.5 x 10<sup>4</sup> cells/well in 96 well plates and starved for 3-6 hours in media with 0.5% FBS at 37°C in a 5% CO<sub>2</sub> incubator. The

-75-

cells were then stimulated with 2.5 ng/ml TGF $\beta$  ligand in the starvation media containing 1% DMSO either in the presence or absence of a test compound of formula (I) and incubated as described above for 24 hours. The media was washed out the following day and the luciferase reporter activity was detected using the LucLite Luciferase Reporter

- 5 Gene Assay kit (Packard, cat. no. 6016911) as recommended. The plates were read on a Wallac Microbeta plate reader, the reading of which was used to determine the IC<sub>50</sub> values of compounds of formula (I) for inhibiting TGF $\beta$ -induced PAI-Luciferase reporter activity in HepG2 cells. Compounds of formula (I) typically exhibited IC<sub>50</sub> values of less 10  $\mu$ M.

- 10 Cytotoxicity was determined using the same cell culture conditions as described above. Specifically, cell viability was determined after overnight incubation with the CytoLite cell viability kit (Packard, cat. no. 6016901). Compounds of formula (I) typically exhibited LD<sub>25</sub> values greater than 10  $\mu$ M.

- 15 **Assay for Evaluating Inhibition of TGF $\beta$  Type I Receptor Kinase Activity in Cells**

The cellular inhibition of activin signaling activity by the test compounds of formula (I) is determined in a similar manner as described above in Example 218 except that 100 ng/ml of activin is added to serum starved cells in place of the 2.5 ng/ml TGF $\beta$ .

#### **Assay for TGF $\beta$ -Induced Collagen Expression**

##### *Preparation of Immortalized Collagen Promotor-Green Fluorescent Protein Cells*

- Fibroblasts are derived from the skin of adult transgenic mice expressing Green Fluorescent Protein (GFP) under the control of the collagen 1A1 promoter (see Krempen, K. et al., Gene Exp. 8: 151-163 (1999)). Cells are immortalized with a temperature sensitive large T antigen that is in an active stage at 33°C. Cells are expanded at 33°C and then transferred to 37°C at which temperature the large T antigen becomes inactive (see Xu, S. et al., Exp. Cell Res. 220: 407-414 (1995)). Over the course of about 4 days and one split, the cells cease proliferating. Cells are then frozen in aliquots sufficient for a
- 25  
30 single 96 well plate.

##### *Assay of TGF $\beta$ -induced Collagen-GFP Expression*

-76-

Cells are thawed, plated in complete DMEM (contains non-essential amino acids, 1mM sodium pyruvate and 2mM L-glutamine) with 10 % fetal calf serum, and then incubated for overnight at 37°C, 5% CO<sub>2</sub>. The cells are trypsinized in the following day and transferred into 96 well format with 30,000 cells per well in 50 µl complete DMEM containing 2 % fetal calf serum, but without phenol red. The cells are incubated at 37°C for 3 to 4 hours to allow them to adhere to the plate. Solutions containing a test compound of formula (I) are then added to wells with no TGFβ (in triplicates), as well as wells with 1 ng/ml TGFβ (in triplicates). DMSO is also added to all of the wells at a final concentration of 0.1%. GFP fluorescence emission at 530 nm following excitation at 485 nm is measured at 48 hours after the addition of solutions containing a test compound on a CytoFluor microplate reader (PerSeptive Biosystems). The data are then expressed as the ratio of TGFβ-induced to non-induced for each test sample.
